# computer graphics

Grosu Olga

#### Introduction to Computer Graphics

- Graphics are defined as any sketch or a drawing or a special network that pictorially represents some meaningful information.
- Computer Graphics is used where a set of images needs to be manipulated or the creation of the image in the form of pixels and is drawn on the computer using programing language.

#### Introduction to Computer Graphics

- Photography, film, entertainment, electronic gadgets, and all other core technologies which are required. It is a vast subject and area in the field of computer science.
- Computer Graphics can be used in UI design, rendering, geometric objects, animation, and many more.

#### **Types of Computer Graphics**

- Raster Graphics: In raster, graphics pixels are used for an image to be drawn. It is also known as a bitmap image in which a sequence of images is into smaller pixels. Basically, a bitmap indicates a large number of pixels together.
- Vector Graphics: In vector graphics,
   mathematical formulae are used to draw
   different types of shapes, lines, objects, and so

#### **INSTRUCTIONS FOR USER**

- ✓ Start by visiting <a href="https://processing.org/download">https://processing.org/download</a> and selecting the Mac, Windows, or Linux version, depending on what machine you have.
- ✓ Installation on **Windows**, you'll have a .zip file.

  Double-click it, and drag the folder inside to a location on your hard disk. It could be Program Files or simply the desktop, but the important thing is for the processing folder to be pulled out of that .zip file. Then double-click **processing.exe** to start.

#### **INSTRUCTIONS FOR USER**

✓ Installation on the Mac OS X version is also a .zip file. Double-click it and drag the Processing icon to the Applications folder. If you're using someone else's machine and can't modify the Applications folder, just drag the application to the desktop. Then doubleclick the Processing icon to start.

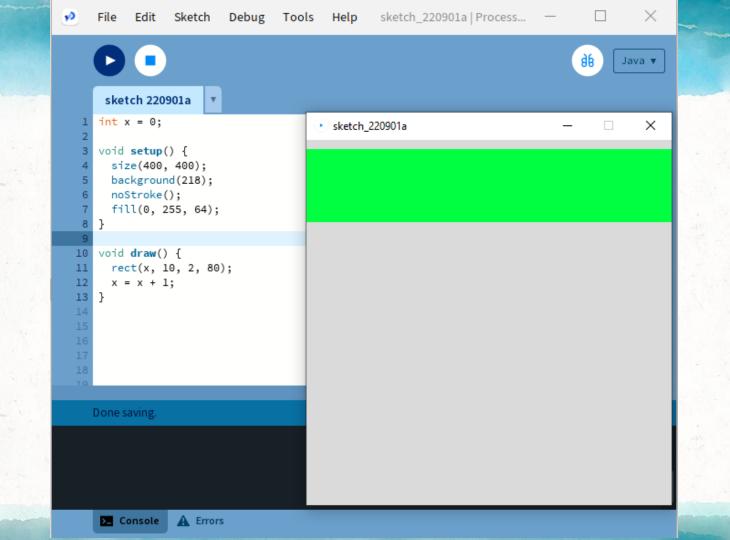

#### **INSTRUCTIONS FOR USER**

✓ Installation on the **Linux** version is a **.tar.gz file**, which should be familiar to most Linux users. Download the file to your home directory, then open a terminal window, and type:

#### tar xvfz processing-xxxx.tgz

(Replace xxxx with the rest of the file's name, which is the version number.) This will create a folder named processing-2.0 or something similar. Then change to that directory: cd processing-xxxx

and run it: ./processing

#### Primitive datatype

boolean	Datatype for the Boolean values	true and false
---------	---------------------------------	----------------

byte Datatype for bytes, 8 bits of information storing numerical values from 127 to

-128

char Datatype for characters, typographic symbols such as A, d, and \$

color Datatype for storing color values

double Datatype for floating-point numbers larger than those that can be stored in a

float

float Data type for floating-point numbers, e

int Datatype for integers, numbers without a decimal point

long Datatype for large integers

## Structure function - setup()

- The setup() function is run once, when the program starts.
- It's used to define initial environment properties such as screen size and to load media such as images and fonts as the program starts.
- There can only be one setup() function for each program and it shouldn't be called again after its initial execution.

# Structure function - setup()

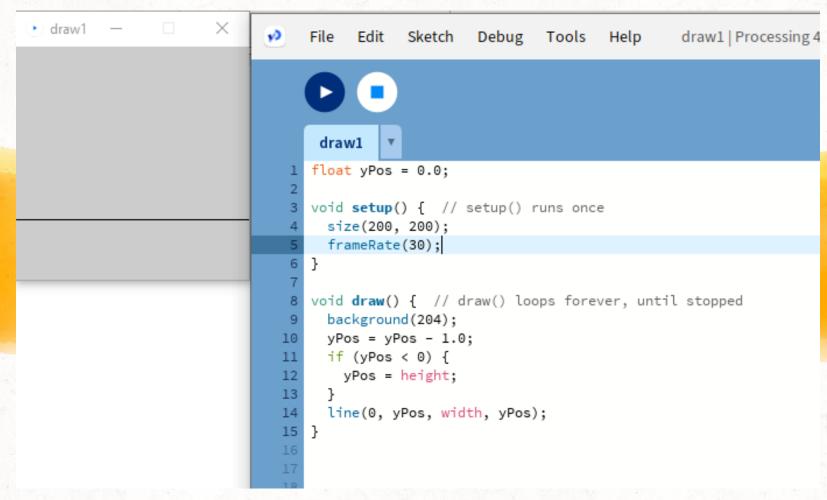

If the sketch is a different dimension than the default, the **size()** function or **fullScreen()** function must be the first line in **setup()**.

**Note:** Variables declared within setup() are not accessible within other functions, including **draw()**.

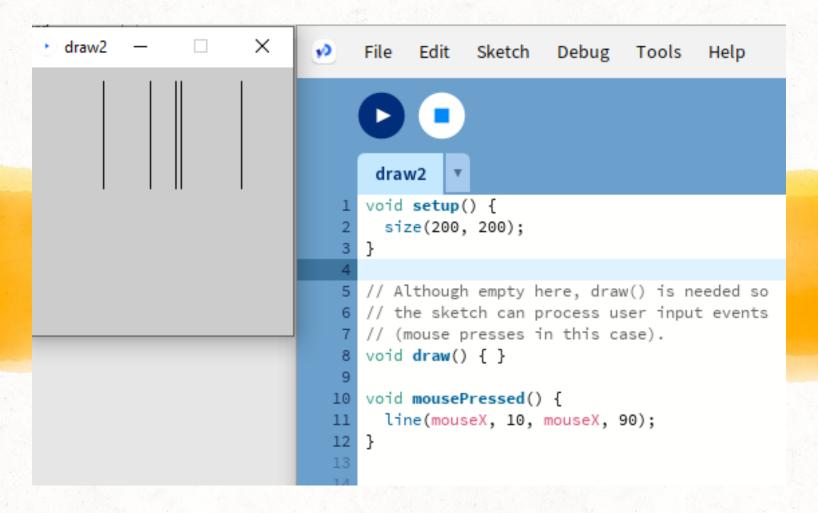

- Called directly after setup(), the draw() function continuously executes the lines of code contained inside its block until the program is stopped or noLoop() is called.
- draw() is called automatically and should never be called explicitly. All Processing programs update the screen at the end of draw(), never earlier.

- To stop the code inside of draw() from running continuously, use noLoop(), redraw() and loop().
- If **noLoop()** is used to stop the code in **draw()** from running, then **redraw()** will cause the code inside **draw()** to run a single time, and **loop()** will cause the code inside **draw()** to resume running continuously.

- The number of times **draw()** executes in each second may be controlled with the **frameRate()** function.
- beginning of the **draw()** loop to clear the contents of the window. Since pixels drawn to the window are cumulative, omitting **background()** may result in unintended results.

- There can only be one draw() function for each sketch, and draw() must exist if you want the code to run continuously, or to process events such as mousePressed().
- Sometimes, you might have an empty call to draw() in your program.

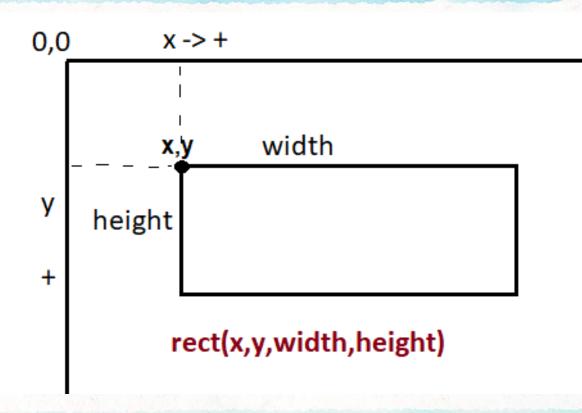

#### Environment function - size()

- Exemple: size(200, 100); size(150, 200, P3D); // Specify P3D renderer
- Defines the dimension of the display window width and height in units of pixels.
- In a program that has the **setup()** function, the **size()** function must be the first line of code inside **setup()**, and the **setup()** function must appear in the code tab with the same name as your sketch folder.

#### 2D primitives function - rect()

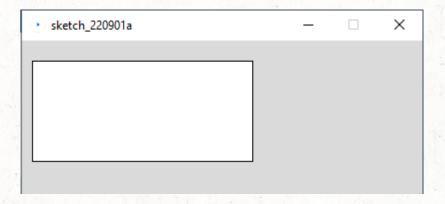

size()

- the first two
   parameters set the
   location of the upper left corner,
- the third sets the width,
- and the fourth sets the height.

#### rect(x,y,width,heigth) - exemple:

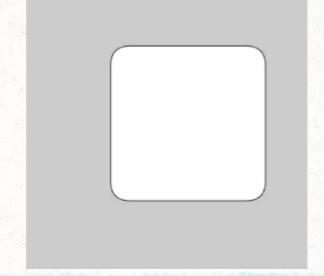

size(400, 400); rect(10, 20, 220, 100);

#### rect(x,y,width,height,radii 4 corners)

- To draw a rounded rectangle,
- add a fifth parameter, which is used as the radius value for all four corners.

```
size(400, 400);
rect(120, 80, 220, 220, 28);
```

## rect(x,y,width,height,tl,tr,bl,br)

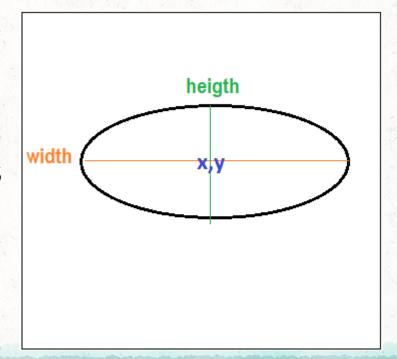

- To use a different radius value for each corner, include eight parameters.
- size(400, 400); rect(120, 80, 220, 220, 12, 24, 48, 72);

- tl=radius for top-left corner
- tr=radius for top-right corner
- bl=radius for bottom-left corner
- br=radius for bottom-right corner

## 2D primitives function - ellipse()

- Draws an ellipse (oval) to the screen.
- An ellipse with equal width and height is a circle.
- By default, the first two parameters set the location, and the third and fourth parameters set the shape's width and height.

#### ellipse(x,y,width,height)

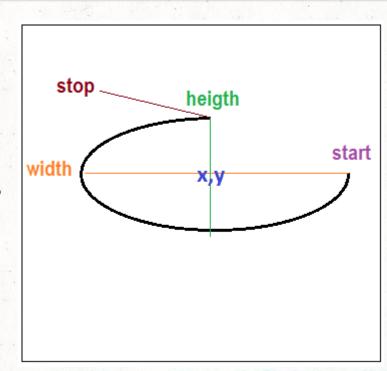

#### 2D primitives function - arc()

Draws an arc to the screen.

arc(x,y,width,height, start,stop)

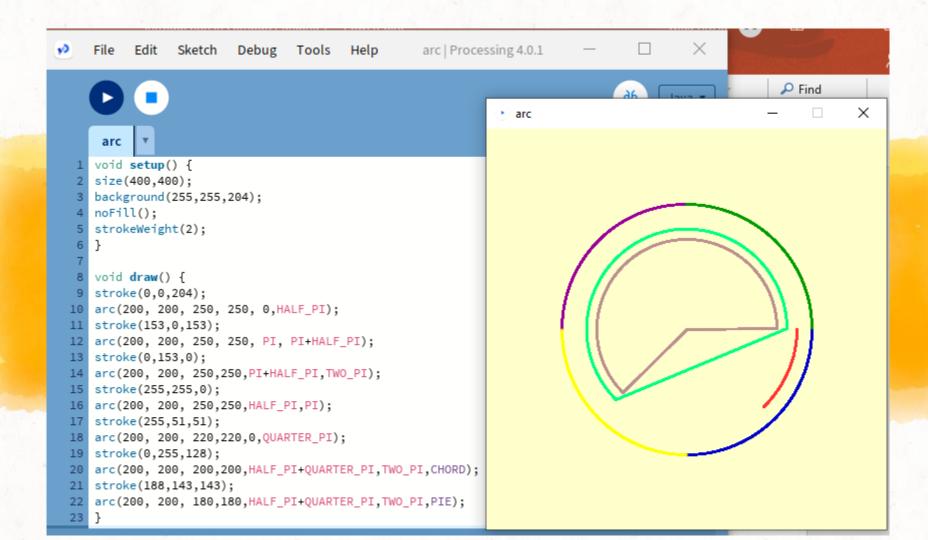

- Arcs are drawn along the outer edge of an ellipse defined.
- By default, the two parameters is the coordinate of the arc's ellipse newt two – width, height of the arc's ellipse by default
- Start=angle to start the arc, specified in radians
- Stop= angle to stop the arc, specified in radians

## 2D primitives function - arc()

arc(x,y,width,height, start, stop, mode)

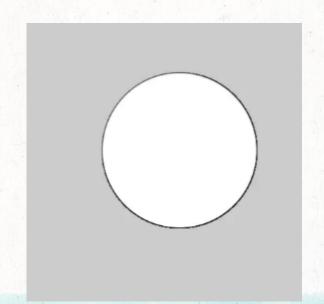

- Constant:
- ► HALF\_PI is a mathematical constant = 1.5707964.
- ▶ PI is a mathematical constant = 3.1415927.
- ► QUARTER\_PI is a mathematical constant = 0.7853982.
- ► TWO\_PI is a mathematical constant = 6.2831855.
- ► TAU is a mathematical constant = 6.2831855.
- Mode= PIE, OPEN, or CHORD (see also -arc())

## 2D primitives function - circle()

- Draws a circle to the screen.
- the first two parameters set the location of the center,
- extent=sets the shape's width and height by default.
- The origin may be changed with the ellipseMode() function.

circle(x, y, extent) circle(224, 184, 220);

## 2D primitives function - square()

- Draws a square to the screen.
- extent= set width and height of the rectangle by default.
- The origin may be changed with the rectMode() function.

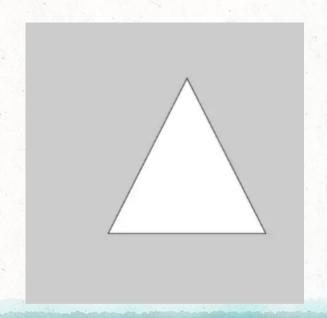

#### square(x, y, extent)

square(120, 100, 220);

#### 2D primitives function - triangle()

- A triangle is a plane created by connecting three points.
- The first two arguments specify the first point,
- the middle two arguments specify the second point,
- and the last two arguments specify the third point.

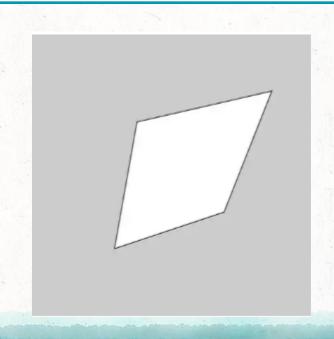

triangle(x1, y1, x2, y2, x3, y3) triangle(120, 300, 232, 80, 344, 300);

## 2D primitives function - quad()

A quad is a quadrilateral, a four sided polygon. **quad(x1, y1, x2, y2, x3, y3, x4, y4)** quad(152, 124, 344, 80, 276, 252, 120, 304);

- It is similar to a rectangle, but the angles between its edges are not constrained to ninety degrees.
- The first pair of parameters (x1,y1) sets the first vertex and the subsequent pairs should proceed clockwise or counter-clockwise around the defined shape.

#### 2D primitives function - line()

#### line(x1, y1, x2, y2)

- Draws a line (a direct path between two points) to the screen.
- ▶ The version of line() with four parameters draws the line in 2D.
- To color a line, use the stroke() function.
- A line cannot be filled, therefore the fill() function will not affect the color of a line.
- 2D lines are drawn with a width of one pixel by default, but this can be changed with the strokeWeight() function.

# line(x1, y1, z1, x2, y2, z2)

- The version with six parameters allows the line to be placed anywhere within XYZ space.
- Drawing this shape in 3D
   with the z parameter
   requires the P3D parameter
   in combination with size() as
   shown in the above example.

```
size(400, 400, P3D);
line(120, 80, 0, 340, 80, 60);
stroke(126);
line(340, 80, 60, 340, 300, 0);
stroke(255);
line(340, 300, 0, 120, 300, -200);
```

#### Also function to use

- fullScreen() or size()
- background()
- <u>stroke()</u>, <u>noStroke()</u>
- fill(), noFill()
- strokeWeight()
- <u>rectMode()</u>
- <u>ellipseMode()</u>
